sse | For a better world of energy

Knowledge Organiser

Energy can be generated in many different ways – these are called ***energy sources***.

Renewable energy sources use the world's natural resources to generate energy e.g. wind, sun and moving water

Non-renewable energy sources use the world's finite resources. These are burnt to generate energy.

Fossil fuels are the most common type of non-renewable energy sources including oil, gas and coal.

Finite resources are things which do not naturally replenish and will eventually run out e.g. oil, gas and coal

When we burn the world's natural resources, it creates ***carbon emissions***. This causes ***air pollution***.
